

Python File Write

Python can write content to a file.

```
text = "This line will end up being in a file called test.txt"

with open('c:/data/test.txt','w') as file:
    file.write(text)
```

after the path, the default value is:

'r' for **read**, this can be left off because it is the default.

'w' **writes** a new file and if the file already exists, will overwrite it

'a' will **append** text to the existing file and not overwrite what is there.

\n will start a new line.

```
text = "\n This line has been appended."

with open('c:/data/test.txt','a') as file:
    file.write(text)
```
